Arithmetic on quantum computers: why do we care?

## Arithmetic on quantum computers: why do we care?

OPEN

### Classically verifiable quantum advantage from a computational Bell test

Gregory D. Kahanamoku-Meyer<sup>1</sup>, Soonwon Choi<sup>1</sup>, Umesh V. Vazirani<sup>2</sup> and Norman Y. Yao

Existing experimental demonstrations of quantum computational advantage have had the limitation that verifying the correctness of the quantum device requires exponentially costly classical computations. Here we propose and analyse an interactive protocol for demonstrating quantum computational advantage, which is efficiently classically verifiable. Our protocol relies on a class of cryptographic tools called trapdoor claw-free functions. Although this type of function has been applied to quantum advantage protocols before, our protocol employs a surprising connection to Bell's inequality to avoid the need for a demanding cryptographic property called the adaptive hardcore bit, while maintaining essentially no increase in the quantum circuit complexity and no extra assumptions. Leveraging the relaxed cryptographic requirements of the protocol, we present two trapdoor claw-free function constructions, based on Rabin's function and the Diffie-Hellman problem, which have not been used in this context before. We also

### Classically verifiable quantum advantage from a computationally untrusted quantum device

#### A Cryptographic Test of Quantumness and Certifiable Randomness from a Single Quantum Device

Gregory D. Kahar

Existing experimental demonstrations of quantum advantage rely on cryptographic tools called the adversary's decommitment property. Leveraging our new model, we propose a new model for the testing of untrusted quantum devices, consisting of a single polynomial time bounded quantum device interacting with a classical polynomial time verifier. In this model, we propose solutions to two tasks—a protocol for efficient classical verification that the untrusted device is "truly quantum" and a protocol for producing certifiable randomness from a single untrusted quantum device. Our solution relies on the existence of a new cryptographic primitive for constraining the power of a quantum device.

### POLYNOMIAL-TIME ALGORITHMS FOR PRIME FACTORIZATION AND DISCRETE LOGARITHMS ON A QUANTUM COMPUTER\*

PETER W. SHOR<sup>†</sup>

**Abstract.** A digital computer is generally believed to be an efficient universal computing device; that is, it is believed able to simulate any physical computing device with an increase in computation time by at most a polynomial factor. This may not be true when quantum mechanics is taken into consideration. This paper considers factoring integers and finding discrete logarithms, two problems which are generally thought to be hard on a classical computer and which have been used as the basis of

### POLYNOM AND DIS

We consider a new model of time bounded quantum computation. We propose solutions to two problems: "truly quantum" and a problem for a quantum device. Our solution relies on quantum devices.

**Abstract.**  
that is, it is believed that it is the best time by at most a constant factor. ]  
consideration. ]  
which are generated by a quantum circuit.

### An Efficient Quantum Factoring Algorithm

Oded Regev\*

### Abstract

We show that  $n$ -bit integers can be factorized by independently running a quantum circuit with  $\tilde{O}(n^{3/2})$  gates for  $\sqrt{n} + 4$  times, and then using polynomial-time classical post-processing. The correctness of the algorithm relies on a number-theoretic heuristic assumption reminiscent of those used in subexponential classical factorization algorithms. It is currently not clear if the

## Background: schoolbook multiplication

The “schoolbook” method:  $xy = \sum_{ij} (2^i x_i)(2^j y_j) = \sum_{ij} 2^{i+j} x_i y_j$

$$\begin{array}{r} \phantom{+} \phantom{1} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \\ \phantom{+} \phantom{1} \phantom{0} \phantom{1} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \\ \phantom{+} \phantom{1} \phantom{0} \phantom{1} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \\ \times \phantom{1} \phantom{0} \phantom{1} \phantom{0} \\ \hline \phantom{+} \phantom{1} \phantom{0} \phantom{1} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \\ \phantom{+} \phantom{1} \phantom{0} \phantom{1} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \\ \phantom{+} \phantom{1} \phantom{0} \phantom{1} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \\ + \phantom{1} \phantom{0} \phantom{1} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \\ \hline \mathbf{1} \ \mathbf{0} \ \mathbf{0} \ \mathbf{0} \ \mathbf{0} \ \mathbf{0} \ \mathbf{1} \ \mathbf{0} \end{array}$$

## Background: schoolbook multiplication

The “schoolbook” method:  $xy = \sum_{ij} (2^i x_i)(2^j y_j) = \sum_{ij} 2^{i+j} x_i y_j$

$$\begin{array}{r} \phantom{+} \phantom{1} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \phantom{0} \phantom{1} \phantom{0} \\ \phantom{+} \phantom{1} \phantom{0} \phantom{0} \phantom{1} \phantom{0} \\ \times \phantom{1} \phantom{0} \phantom{1} \phantom{0} \\ \hline \phantom{+} \phantom{1} \phantom{0} \phantom{0} \phantom{1} \phantom{0} \\ + \phantom{1} \phantom{0} \phantom{0} \phantom{1} \phantom{0} \\ \hline \mathbf{1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0} \end{array}$$

Running time:  $\mathcal{O}(n^2)$  operations

## Background: schoolbook multiplication

Given two  $n$ -bit numbers  $x$  and  $y$ , what if we use base  $b = 2^{n/2}$ ?

$$\begin{array}{r} \phantom{\times} \phantom{y_1} \phantom{y_0} \phantom{x_1} \phantom{x_0} \\ \times \phantom{y_1} \phantom{y_0} \phantom{x_1} \phantom{x_0} \\ \hline \phantom{\times} \phantom{y_1} \phantom{y_0} x_0 y_0 \\ \phantom{\times} \phantom{y_1} x_1 y_0 \\ \phantom{\times} x_0 y_1 \\ + \phantom{x_1} x_1 y_1 \\ \hline \end{array}$$

## Background: schoolbook multiplication

Given two  $n$ -bit numbers  $x$  and  $y$ , what if we use base  $b = 2^{n/2}$ ?

$$\begin{array}{r} \phantom{\times} \phantom{y_1} x_1 \phantom{y_0} x_0 \\ \times \phantom{y_1} y_1 \phantom{y_0} y_0 \\ \hline \phantom{\times} \phantom{y_1} \phantom{x_1} x_0 y_0 \\ \phantom{\times} \phantom{y_1} x_1 y_0 \\ \phantom{\times} \phantom{y_1} x_0 y_1 \\ + \phantom{\times} x_1 y_1 \\ \hline \end{array}$$

$$xy = x_1 y_1 b^2 + x_0 y_1 b + x_1 y_0 b + x_0 y_0$$

## Background: schoolbook multiplication

Given two  $n$ -bit numbers  $x$  and  $y$ , what if we use base  $b = 2^{n/2}$ ?

$$\begin{array}{r} \phantom{\times} \phantom{y_1} \phantom{y_0} \phantom{x_1} \phantom{x_0} \\ \times \phantom{y_1} \phantom{y_0} \phantom{x_1} \phantom{x_0} \\ \hline \phantom{\times} \phantom{y_1} \phantom{y_0} x_0 y_0 \\ \phantom{\times} \phantom{y_1} x_1 y_0 \\ \phantom{\times} \phantom{y_0} x_0 y_1 \\ + \phantom{\times} x_1 y_1 \\ \hline \end{array}$$

$$xy = x_1 y_1 b^2 + x_0 y_1 b + x_1 y_0 b + x_0 y_0$$

Time remains  $\mathcal{O}(n^2)$ , because  $4(n/2)^2 = n^2$

## Background: Karatsuba multiplication

$$xy = x_1y_1b^2 + (x_0y_1 + x_1y_0)b + x_0y_0$$

## Background: Karatsuba multiplication

$$xy = x_1y_1b^2 + (x_0y_1 + x_1y_0)b + x_0y_0$$

**Observation:**  $x_0y_1 + x_1y_0 = (x_1 + x_0)(y_1 + y_0) - x_1y_1 - x_0y_0$

## Background: Karatsuba multiplication

$$xy = x_1y_1b^2 + (x_0y_1 + x_1y_0)b + x_0y_0$$

**Observation:**  $x_0y_1 + x_1y_0 = (x_1 + x_0)(y_1 + y_0) - x_1y_1 - x_0y_0$

Can compute  $xy$  with only **three** multiplications of size  $\log b = n/2$ :

1.  $x_1y_1$
2.  $x_0y_0$
3.  $(x_1 + x_0)(y_1 + y_0)$

## Background: Karatsuba multiplication

$$xy = x_1y_1b^2 + (x_0y_1 + x_1y_0)b + x_0y_0$$

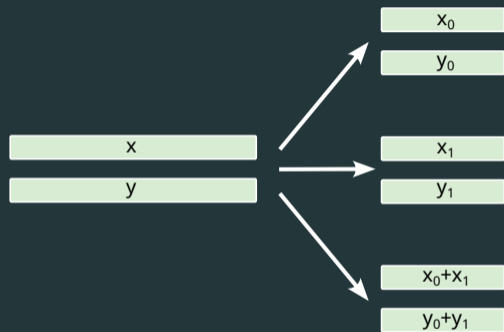

**Observation:**  $x_0y_1 + x_1y_0 = (x_1 + x_0)(y_1 + y_0) - x_1y_1 - x_0y_0$

Can compute  $xy$  with only **three** multiplications of size  $\log b = n/2$ :

1.  $x_1y_1$
2.  $x_0y_0$
3.  $(x_1 + x_0)(y_1 + y_0)$

Computational cost:  $3(n/2)^2 = \frac{3}{4}n^2 = \mathcal{O}(n^2)$

$$xyz = \sum_{i,j,k} 2^i 2^j 2^k x_i y_j z_k$$

$$\exp\left(\frac{2\pi ixyz}{2^n}\right) = \prod_{i,j,k} \exp\left(\frac{2\pi i 2^{i+j+k}}{2^n} x_i y_j z_k\right)$$

## A fundamentally quantum way of doing arithmetic

How do we apply  $\exp\left(\frac{2\pi ixyz}{2^n}\right)$ ?

$$xyz = \sum_{i,j,k} 2^i 2^j 2^k x_i y_j z_k$$

$$\exp\left(\frac{2\pi ixyz}{2^n}\right) = \prod_{i,j,k} \exp\left(\frac{2\pi i 2^{i+j+k}}{2^n} x_i y_j z_k\right)$$

$x_i, y_j, z_k$  are binary values—apply phase only if they all are equal to 1!

## A fundamentally quantum way of doing arithmetic

How do we apply  $\exp\left(\frac{2\pi ixyz}{2^n}\right)$ ?

$$xyz = \sum_{i,j,k} 2^i 2^j 2^k x_i y_j z_k$$

$$\exp\left(\frac{2\pi ixyz}{2^n}\right) = \prod_{i,j,k} \exp\left(\frac{2\pi i 2^{i+j+k}}{2^n} x_i y_j z_k\right)$$

$x_i, y_j, z_k$  are binary values—apply phase only if they all are equal to 1!

A series of  $CCR_\phi$  gates between the bits of  $|x\rangle$ ,  $|y\rangle$ , and  $|z\rangle$ !

## A fundamentally quantum way of doing arithmetic

$$\exp\left(\frac{2\pi ixyz}{2^n}\right) = \prod_{i,j,k} \exp\left(\frac{2\pi i2^{i+j+k}}{2^n} x_i y_j z_k\right)$$

The downside:

## A fundamentally quantum way of doing arithmetic

$$\exp\left(\frac{2\pi ixyz}{2^n}\right) = \prod_{i,j,k} \exp\left(\frac{2\pi i2^{i+j+k}}{2^n} x_i y_j z_k\right)$$

The downside: For  $n$ -bit numbers, this requires  $n^3$  gates!

## A fundamentally quantum way of doing arithmetic

$$\exp\left(\frac{2\pi ixyz}{2^n}\right) = \prod_{i,j,k} \exp\left(\frac{2\pi i2^{i+j+k}}{2^n} x_i y_j z_k\right)$$

**The downside:** For  $n$ -bit numbers, this requires  $n^3$  gates!

---

A modest improvement: classical-quantum multiplication  $\mathcal{U}(a) |x\rangle |0\rangle = |x\rangle |ax\rangle$

## A fundamentally quantum way of doing arithmetic

$$\exp\left(\frac{2\pi ixyz}{2^n}\right) = \prod_{i,j,k} \exp\left(\frac{2\pi i2^{i+j+k}}{2^n} x_i y_j z_k\right)$$

**The downside:** For  $n$ -bit numbers, this requires  $n^3$  gates!

---

A modest improvement: classical-quantum multiplication  $\mathcal{U}(a) |x\rangle |0\rangle = |x\rangle |ax\rangle$

$$\exp\left(\frac{2\pi iaxz}{2^n}\right) = \prod_{i,j} \exp\left(\frac{2\pi ia2^{i+j}}{2^n} x_i z_j\right)$$

Here:  $\mathcal{O}(n^2)$  controlled phase rotations (matches Schoolbook algorithm)

**Main question:** Can we combine fast multiplication with Fourier arithmetic to get the benefits of both?

# Fast classical-quantum multiplication

Goal:  $\mathcal{U}(a) |x\rangle |0\rangle = |x\rangle |ax\rangle$

# Fast classical-quantum multiplication

Goal: Apply phase  $\exp\left(\frac{2\pi ia}{2^n}xz\right)$ ;  $x$  and  $z$  are quantum

# Fast classical-quantum multiplication

Goal: Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

# Fast classical-quantum multiplication

**Goal:** Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

# Fast classical-quantum multiplication

Goal: Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

Previously:

$$\exp(i\phi xz) = \prod_{i,j} \exp\left(i\phi 2^{i+j} x_i z_j\right)$$

# Fast classical-quantum multiplication

**Goal:** Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

**Karatsuba:**

$$xz = 2^n x_1 z_1 + 2^{n/2} ((x_0 + x_1)(z_0 + z_1) - x_0 z_0 - x_1 z_1) + x_0 z_0$$

# Fast classical-quantum multiplication

**Goal:** Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

**Plugging in Karatsuba:**

$$\begin{aligned}\exp(i\phi xz) &= \exp(i\phi 2^n x_1 z_1) \\ &\quad \cdot \exp(i\phi x_0 z_0) \\ &\quad \cdot \exp\left(i\phi 2^{n/2}((x_0 + x_1)(z_0 + z_1) - x_0 z_0 - x_1 z_1)\right)\end{aligned}$$

# Fast classical-quantum multiplication

Goal: Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

Plugging in Karatsuba:

$$\begin{aligned}\exp(i\phi xz) &= \exp(i\phi 2^n x_1 z_1) \\ &\quad \cdot \exp(i\phi x_0 z_0) \\ &\quad \cdot \exp\left(i\phi 2^{n/2}((x_0 + x_1)(z_0 + z_1) - x_0 z_0 - x_1 z_1)\right)\end{aligned}$$

How are we supposed to **reuse** values in the *phase*?

# Fast classical-quantum multiplication

**Goal:** Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

**Karatsuba:**

$$xz = 2^n x_1 z_1 + 2^{n/2} ((x_0 + x_1)(z_0 + z_1) - x_0 z_0 - x_1 z_1) + x_0 z_0$$

# Fast classical-quantum multiplication

**Goal:** Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

**Re-ordering Karatsuba:**

$$xz = (2^n - 2^{n/2})x_1z_1 + 2^{n/2}(x_0 + x_1)(z_0 + z_1) + (1 - 2^{n/2})x_0z_0$$

# Fast classical-quantum multiplication

Goal: Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

Plugging in reordered Karatsuba:

$$\begin{aligned} \exp(i\phi xz) &= \exp\left(i\phi(2^n - 2^{n/2})x_1z_1\right) \\ &\quad \cdot \exp\left(i\phi(1 - 2^{n/2})x_0z_0\right) \\ &\quad \cdot \exp\left(i\phi 2^{n/2}(x_0 + x_1)(z_0 + z_1)\right) \end{aligned}$$

# Fast classical-quantum multiplication

Goal: Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

Plugging in reordered Karatsuba:

$$\begin{aligned}\exp(i\phi xz) &= \exp(i\phi_1 x_1 z_1) \\ &\quad \cdot \exp(i\phi_2 x_0 z_0) \\ &\quad \cdot \exp(i\phi_3 (x_0 + x_1)(z_0 + z_1))\end{aligned}$$

$$\phi_1 = (2^n - 2^{n/2})\phi$$

$$\phi_2 = (1 - 2^{n/2})\phi$$

$$\phi_3 = 2^{n/2}\phi$$

# Fast classical-quantum multiplication

Goal: Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

We want to split the phase  $\phi xz$  into the sum of many phases, which are easy to implement.

Plugging in reordered Karatsuba:

$$\begin{aligned} \exp(i\phi xz) &= \exp(i\phi_1 x_1 z_1) & \phi_1 &= (2^n - 2^{n/2})\phi \\ &\cdot \exp(i\phi_2 x_0 z_0) & \phi_2 &= (1 - 2^{n/2})\phi \\ &\cdot \exp(i\phi_3 (x_0 + x_1)(z_0 + z_1)) & \phi_3 &= 2^{n/2}\phi \end{aligned}$$

Each of these has the same structure, but on half as many qubits  $\rightarrow$  do it recursively!

# Fast classical-quantum multiplication

Goal: Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

$$\exp(i\phi xz) = \exp(i\phi_1 x_1 z_1)$$

$$\cdot \exp(i\phi_2 x_0 z_0)$$

$$\cdot \exp(i\phi_3 (x_0 + x_1)(z_0 + z_1))$$

$$\phi_1 = (2^n - 2^{n/2})\phi$$

$$\phi_2 = (1 - 2^{n/2})\phi$$

$$\phi_3 = 2^{n/2}\phi$$

Recursion relation:  $T(n) = 3T(n/2)$

# Fast classical-quantum multiplication

Goal: Implement  $\text{PhaseProduct}(\phi) |x\rangle |z\rangle = \exp(i\phi xz) |x\rangle |z\rangle$

$$\exp(i\phi xz) = \exp(i\phi_1 x_1 z_1)$$

$$\cdot \exp(i\phi_2 x_0 z_0)$$

$$\cdot \exp(i\phi_3 (x_0 + x_1)(z_0 + z_1))$$

$$\phi_1 = (2^n - 2^{n/2})\phi$$

$$\phi_2 = (1 - 2^{n/2})\phi$$

$$\phi_3 = 2^{n/2}\phi$$

Recursion relation:  $T(n) = 3T(n/2) \Rightarrow \mathcal{O}(n^{\log_2 3}) = \mathcal{O}(n^{1.58\dots})$  gates!

## How many qubits do we need?

Splitting registers  $|x\rangle \rightarrow |x_1\rangle |x_0\rangle$  and  $|z\rangle \rightarrow |z_1\rangle |z_0\rangle$ , can immediately do

- $\exp(i\phi_1 x_1 z_1)$
- $\exp(i\phi_2 x_0 z_0)$

## How many qubits do we need?

Splitting registers  $|x\rangle \rightarrow |x_1\rangle |x_0\rangle$  and  $|z\rangle \rightarrow |z_1\rangle |z_0\rangle$ , can immediately do

- $\exp(i\phi_1 x_1 z_1)$
- $\exp(i\phi_2 x_0 z_0)$

What about  $\exp(i\phi_3(x_0 + x_1)(z_0 + z_1))$ ?

## How many qubits do we need?

Splitting registers  $|x\rangle \rightarrow |x_1\rangle |x_0\rangle$  and  $|z\rangle \rightarrow |z_1\rangle |z_0\rangle$ , can immediately do

- $\exp(i\phi_1 x_1 z_1)$
- $\exp(i\phi_2 x_0 z_0)$

What about  $\exp(i\phi_3(x_0 + x_1)(z_0 + z_1))$ ?

Use quantum addition circuits.

## How many qubits do we need?

Splitting registers  $|x\rangle \rightarrow |x_1\rangle |x_0\rangle$  and  $|z\rangle \rightarrow |z_1\rangle |z_0\rangle$ , can immediately do

- $\exp(i\phi_1 x_1 z_1)$
- $\exp(i\phi_2 x_0 z_0)$

What about  $\exp(i\phi_3(x_0 + x_1)(z_0 + z_1))$ ?

Use quantum addition circuits.

But, **addition is reversible**  $\rightarrow$  do it *in-place*! E.g.  $|x_1\rangle |x_0\rangle \rightarrow |x_1\rangle |x_0 + x_1\rangle$

## Fast quantum-quantum multiplication

Goal:  $\mathcal{U} |x\rangle |y\rangle |0\rangle = |x\rangle |y\rangle |xy\rangle$

## Fast quantum-quantum multiplication

Goal: Apply phase  $\exp\left(\frac{2\pi i}{2^n}xyz\right)$ ;  $x$ ,  $y$ , and  $z$  are quantum

# Fast quantum-quantum multiplication

Goal: Implement  $\text{PhaseTripleProduct}(\phi) |x\rangle |y\rangle |z\rangle = \exp(i\phi xyz) |x\rangle |y\rangle |z\rangle$

# Fast quantum-quantum multiplication

Goal: Implement  $\text{PhaseTripleProduct}(\phi) |x\rangle |y\rangle |z\rangle = \exp(i\phi xyz) |x\rangle |y\rangle |z\rangle$

Previously:

$$\exp(i\phi xyz) = \prod_{i,j,k} \exp\left(i\phi 2^{i+j+k} x_i y_j z_k\right) \quad (n^3 \text{ doubly-controlled phase rotations})$$

# Fast quantum-quantum multiplication

Goal: Implement  $\text{PhaseTripleProduct}(\phi) |x\rangle |y\rangle |z\rangle = \exp(i\phi xyz) |x\rangle |y\rangle |z\rangle$

Previously:

$$\exp(i\phi xyz) = \prod_{i,j,k} \exp\left(i\phi 2^{i+j+k} x_i y_j z_k\right) \quad (n^3 \text{ doubly-controlled phase rotations})$$

Question: How would you classically compute a triple product like  $xyz$ ?

# Fast quantum-quantum multiplication

Goal: Implement  $\text{PhaseTripleProduct}(\phi) |x\rangle |y\rangle |z\rangle = \exp(i\phi xyz) |x\rangle |y\rangle |z\rangle$

Previously:

$$\exp(i\phi xyz) = \prod_{i,j,k} \exp\left(i\phi 2^{i+j+k} x_i y_j z_k\right) \quad (n^3 \text{ doubly-controlled phase rotations})$$

**Question:** How would you classically compute a triple product like  $xyz$ ?

**Answer:** Use parentheses!  $xyz = x(yz)$ .

# Fast quantum-quantum multiplication

Goal: Implement  $\text{PhaseTripleProduct}(\phi) |x\rangle |y\rangle |z\rangle = \exp(i\phi xyz) |x\rangle |y\rangle |z\rangle$

Previously:

$$\exp(i\phi xyz) = \prod_{i,j,k} \exp\left(i\phi 2^{i+j+k} x_i y_j z_k\right) \quad (n^3 \text{ doubly-controlled phase rotations})$$

**Question:** How would you classically compute a triple product like  $xyz$ ?

**Answer:** Use parentheses!  $xyz = x(yz)$ . Then asymptotic cost is the same

# Fast quantum-quantum multiplication

Goal: Implement  $\text{PhaseTripleProduct}(\phi) |x\rangle |y\rangle |z\rangle = \exp(i\phi xyz) |x\rangle |y\rangle |z\rangle$

Previously:

$$\exp(i\phi xyz) = \prod_{i,j,k} \exp\left(i\phi 2^{i+j+k} x_i y_j z_k\right) \quad (n^3 \text{ doubly-controlled phase rotations})$$

**Question:** How would you classically compute a triple product like  $xyz$ ?

**Answer:** Use parentheses!  $xyz = x(yz)$ . Then asymptotic cost is the same

Doesn't work in the phase!!

Goal: Compute  $xyz$  “all at once”

Goal: Compute  $xyz$  “all at once”

Before

$$p(b) = x(b)z(b)$$

$p(b)$  has degree  $q = 2k - 1$

Goal: Compute  $xyz$  “all at once”

Before

$$p(b) = x(b)z(b)$$

$p(b)$  has degree  $q = 2k - 1$

Now

$$p(b) = x(b)y(b)z(b)$$

$p(b)$  has degree  $q = 3k - 2$

## Example: Generalizing Karatsuba's method

For  $k = 2$ , we have  $q = 4$ . Using  $w_i \in \{0, \infty, 1, -1\}$ :

## Example: Generalizing Karatsuba's method

For  $k = 2$ , we have  $q = 4$ . Using  $w_i \in \{0, \infty, 1, -1\}$ :

$$\begin{aligned}xyz &= (2^{3n/2} - 2^{n/2})x_1y_1z_1 \\ &+ \frac{1}{2}(2^n + 2^{n/2})(x_0 + x_1)(y_0 + y_1)(z_0 + z_1) \\ &+ \frac{1}{2}(2^n - 2^{n/2})(x_0 - x_1)(y_0 - y_1)(z_0 - z_1) \\ &+ (1 - 2^n)x_0y_0z_0\end{aligned}$$

## Example: Generalizing Karatsuba's method

For  $k = 2$ , we have  $q = 4$ . Using  $w_i \in \{0, \infty, 1, -1\}$ :

$$\begin{aligned}xyz &= (2^{3n/2} - 2^{n/2})x_1y_1z_1 \\ &+ \frac{1}{2}(2^n + 2^{n/2})(x_0 + x_1)(y_0 + y_1)(z_0 + z_1) \\ &+ \frac{1}{2}(2^n - 2^{n/2})(x_0 - x_1)(y_0 - y_1)(z_0 - z_1) \\ &+ (1 - 2^n)x_0y_0z_0\end{aligned}$$

Only 4 multiplications of length  $n/2$  instead of 8!

## Example: Generalizing Karatsuba's method

Only 4 multiplications of length  $n/2$ , instead of 8!

Recursion relation:  $T(n) \sim 4T(n/2)$

## Example: Generalizing Karatsuba's method

Only 4 multiplications of length  $n/2$ , instead of 8!

Recursion relation:  $T(n) \sim 4T(n/2)$  thus:  $T(n) = \mathcal{O}(n^2)$

## Example: Generalizing Karatsuba's method

Only 4 multiplications of length  $n/2$ , instead of 8!

Recursion relation:  $T(n) \sim 4T(n/2)$  thus:  $T(n) = \mathcal{O}(n^2)$

---

As before:  $k > 2$  is faster.

These runtimes are achieved with 2 ancilla qubits.

$k$	Gates $\mathcal{O}(n^{\log_k(3k-2)})$
1*	$\mathcal{O}(n^3)$
2	$\mathcal{O}(n^2)$
3	$\mathcal{O}(n^{1.77\dots})$
4	$\mathcal{O}(n^{1.66\dots})$
5	$\mathcal{O}(n^{1.59\dots})$
6	$\mathcal{O}(n^{1.55\dots})$
$\vdots$	$\vdots$

## Application: efficiently-verifiable quantum advantage

Protocol for a “proof of quantumness” requires evaluating  $f(x) = x^2 \bmod N$

## Application: efficiently-verifiable quantum advantage

3. Apply  $\text{QFT}_{2^{n-m}}$  on final  $n - m$  qubits

# Fast exact quantum Fourier transform

[Cleve and Watrous 2000]: QFT can be defined recursively.

For any  $m < n$ , we may implement  $\text{QFT}_{2^n}$ :

1. Apply  $\text{QFT}_{2^m}$  on first  $m$  qubits
2. Apply phase rotation  $2\pi xz/2^n$ 
  - $|x\rangle$  is value of first  $m$  qubits
  - $|z\rangle$  is value of final  $n - m$  qubits
3. Apply  $\text{QFT}_{2^{n-m}}$  on final  $n - m$  qubits

Immediately gives us sub-quadratic exact QFT using only 1 ancilla.

# Depth considerations

Parallelization is natural.

# Depth considerations

Parallelization is natural.

We have  $k$  sub-registers to work with—can do  $k$  sub-products in parallel.

# Depth considerations

Parallelization is natural.

We have  $k$  sub-registers to work with—can do  $k$  sub-products in parallel.

**Depth:** PhaseProduct in  $\mathcal{O}(n^{\log_k 2})$  and PhaseTripleProduct in  $\mathcal{O}(n^{\log_k 3})$   
using a few more ancillas

# Depth considerations

Parallelization is natural.

We have  $k$  sub-registers to work with—can do  $k$  sub-products in parallel.

**Challenge for multiply:** How to do the QFT in sublinear depth with even  $\mathcal{O}(n)$  ancillas?

## Application: Shor's algorithm

For Shor's algorithm:  $\mathcal{O}(n)$  modular classical-quantum multiplications

## Application: Shor's algorithm

For Shor's algorithm:  $\mathcal{O}(n)$  modular classical-quantum multiplications

Using phase modulo and  $k = 4$  multiplier:

Gates:  $\mathcal{O}(n^{2.4})$

Total qubits:  $2n + \mathcal{O}(\log(n/\epsilon))$

(Here  $\epsilon$  is error across the whole algorithm)

# Summary

## Classical-quantum

1 ancilla qubit

$k$	Gates
2	$\mathcal{O}(n^{1.58\dots})$
3	$\mathcal{O}(n^{1.46\dots})$
4	$\mathcal{O}(n^{1.40\dots})$
$\vdots$	$\vdots$

## Quantum-quantum

2 ancilla qubits

$k$	Gates
2	$\mathcal{O}(n^2)$
3	$\mathcal{O}(n^{1.77\dots})$
4	$\mathcal{O}(n^{1.66\dots})$
$\vdots$	$\vdots$

# Summary

## Classical-quantum

1 ancilla qubit

$k$	Gates
2	$\mathcal{O}(n^{1.58\dots})$
3	$\mathcal{O}(n^{1.46\dots})$
4	$\mathcal{O}(n^{1.40\dots})$
$\vdots$	$\vdots$

## Quantum-quantum

2 ancilla qubits

$k$	Gates
2	$\mathcal{O}(n^2)$
3	$\mathcal{O}(n^{1.77\dots})$
4	$\mathcal{O}(n^{1.66\dots})$
$\vdots$	$\vdots$

### Implications:

**Shor's algorithm:**  $\mathcal{O}(n^{2.4})$  gates using  
 $2n + \mathcal{O}(\log n)$  qubits

# Summary

## Classical-quantum

1 ancilla qubit

$k$	Gates
2	$\mathcal{O}(n^{1.58\dots})$

## What about all the arbitrary rotation gates?

In error-corrected setting, arbitrary rotation gates need to be synthesized.

## What about all the arbitrary rotation gates?

In error-corrected setting, arbitrary rotation gates need to be synthesized.

**Idea:** “convert” some rotation gates into e.g. Toffolis; easier to synthesize

## What about all the arbitrary rotation gates?

In error-corrected setting, arbitrary rotation gates need to be synthesized.

**Idea:** “convert” some rotation gates into e.g. Toffolis; easier to synthesize

All rotations are in the **base case**: 32-bit (say) PhaseProduct  $\phi x'z'$

## What about all the arbitrary rotation gates?

In error-corrected setting, arbitrary rotation gates need to be synthesized.

**Idea:** “convert” some rotation gates into e.g. Toffolis; easier to synthesize

All rotations are in the **base case**: 32-bit (say) PhaseProduct  $\phi x'z'$

### Direct (schoolbook)

Apply  $32^2 = 1024$   $CR_\phi$  gates

### $CR_\phi$ optimized

1. Compute  $|x'z'\rangle$  via a regular digital multiplier circuit
2. Apply phase rotations on the output
3. Uncompute  $|x'z'\rangle$

## What about all the arbitrary rotation gates?

### $CR_\phi$ optimized

1. Compute  $|x'z'\rangle$  via a regular digital multiplier circuit
2. Apply phase rotations on the output
3. Uncompute  $|x'z'\rangle$

$1024 CR_\phi \rightarrow 64 R_\phi$  plus  $\sim 2048$  Toffoli

So far: have been using phase

$$\exp\left(2\pi i \frac{xyz}{2^n}\right)$$

So far: have been using phase

$$\exp\left(2\pi i \frac{xyz}{2^n}\right)$$

(denominator matches order of QFT)

So far: have been using phase

$$\exp\left(2\pi i \frac{xyz}{2^n}\right)$$

(denominator matches order of QFT)

**Observation:**

$$\exp\left(2\pi i \frac{xyz}{N}\right) = \exp\left(2\pi i \frac{(xy \bmod N)z}{N}\right)$$

# Modular arithmetic

**Goal:** only use  $n$  bits for output modulo  $N$

Observation:

$$\exp\left(2\pi i \frac{xyz}{N}\right) = \exp\left(2\pi i \frac{(xy \bmod N)z}{N}\right)$$

Define

$$w = \frac{xy \bmod N}{N}$$

# Modular arithmetic

**Goal:** only use  $n$  bits for output modulo  $N$

Observation:

$$\exp\left(2\pi i \frac{xyz}{N}\right) = \exp\left(2\pi i \frac{(xy \bmod N)z}{N}\right)$$

Define

$$w = \frac{xy \bmod N}{N}$$

Now, multiplication:

$$|x\rangle |0\rangle \rightarrow |x\rangle |w\rangle$$

# Modular arithmetic

**Goal:** only use  $n$  bits for output modulo  $N$

Observation:

$$\exp\left(2\pi i \frac{xyz}{N}\right) = \exp\left(2\pi i \frac{(xy \bmod N)z}{N}\right)$$

Define

$$w = \frac{xy \bmod N}{N}$$

Now, multiplication:

$$|x\rangle |0\rangle \rightarrow |x\rangle |w\rangle$$

Output register requires  $n + \mathcal{O}(\log(1/\epsilon))$  qubits

# Fast classical-quantum multiplication: algorithm

PhaseProduct( $\phi$ ,  $|x\rangle$ ,  $|z\rangle$ )

---

**Input:** Quantum state  $|x\rangle |z\rangle$ , classical value  $\phi$

**Output:** Quantum state  $\exp(i\phi xz) |x\rangle |z\rangle$

1. Split  $|x\rangle$  and  $|z\rangle$  in half, as  $|x_1\rangle |x_0\rangle$  and  $|z_1\rangle |z_0\rangle$
2. Apply PhaseProduct( $(2^n - 2^{n/2})\phi$ ,  $|x_1\rangle$ ,  $|z_1\rangle$ )
3. Apply PhaseProduct( $(1 - 2^{n/2})\phi$ ,  $|x_0\rangle$ ,  $|z_0\rangle$ )
4. Add  $|x_1\rangle$  to  $|x_0\rangle$ , and  $|z_1\rangle$  to  $|z_0\rangle$ . Registers now hold  $|x_1\rangle |x_0 + x_1\rangle |z_1\rangle |z_0 + z_1\rangle$ .
5. Apply PhaseProduct( $2^{n/2}\phi$ ,  $|x_0 + x_1\rangle$ ,  $|z_0 + z_1\rangle$ ).
6. Subtract  $|x_1\rangle$ ,  $|z_1\rangle$  to return to registers to  $|x_1\rangle |x_0\rangle |z_1\rangle |z_0\rangle$ .
